

# Problem 1

a) TRUE.

$$L(D_1) = L(D_2) \Rightarrow \overline{L(D_1)} \cap L(D_2) = \emptyset$$

$$\text{and } L(D_1) \cap \overline{L(D_2)} = \emptyset$$

↑  
can be computed  
in quadratic time

↑ checking emptiness can be  
done via breadth-first-search.

b) False.  $\emptyset$  and  $\Sigma^*$   $\notin$   $NE$ -complete

but  $\emptyset$  and  $\Sigma^* = L \in NL$ .

c) True. Proof by contradiction.

For each  $B$  we need a different computable function  $f_B$  for the reduction.  
there are uncountably many  $B$  but only countably many  
computable functions.

d) False.

Let  $A_2 = \{w \in \{0,1\}^* \mid w \text{ starts with } 1\}$

$A_1 = \{w \in \{0,1\}^* \mid |w| \text{ is even}\}$

Clearly  $A_1, A_2 \in L$  so  $A_1 \leq_L A_2$ .

But  $A_2 \in TIME(1)$  while  $A_1 \in TIME(n^2)$   ~~$\notin TIME(n)$~~   
 $\notin TIME(o(n))$ .

It is not enough to say that  $A_1 \leq_L A_2$  implies that  $A_1 \in TIME(t(n) \cdot m^{O(1)})$   
because it could exist a direct algorithm for  $A_1$  that is faster than using  
the reduction. You need to give a counter-example!

## Problem 1 (cont)

e) TRUE. Call the language  $A$ .

$$\bar{A} \in NL.$$

For each final state  $q \in F$  initial state  
if there exists path from  $s$  to  $q$  then accept  $\leftarrow$  = PATH.  
↓  
in the DFA  
}  
reject

$$\text{So } \bar{A} \leq_L \text{PATH} \Rightarrow A \leq_L \overline{\text{PATH}} \Rightarrow A \in \text{co-NL} = NL.$$

Now we show that  $A \in NL$ -complete via  $\overline{\text{PATH}} \leq_L A$

Take the graph to be the DFA. Take  $s$  to be the initial state and  $t$  to be the only final state. Compute the maximum degree  $d$  of the graph. Since  $d \leq \text{number of nodes} - 1$  we can store  $d$  (and compute it) in log space.

Let  $\Sigma = \{1, 2, \dots, d\}$  and label the edges from a node  $u$  in order from 1 to the degree of  $u$ . If  $\text{degree}(u) \leq d-1$  then add transitions from  $u$  to a new dead state with symbols  $\text{degree}(u)+1, \text{degree}(u)+2, \dots, d$ .

This can also be done in log-space.

## Problem 2:

SUBSET-SUM

ELEMENTS  $\{z_1, z_2, \dots, z_n\}$

FIND SUBSET THAT SUMS TO  $Y$ .

$$A = \begin{bmatrix} z_1 & z_2 & \dots & z_n \\ -z_1 & -z_2 & \dots & -z_n \end{bmatrix}$$

0-1 INT. PROGRAMMING

$$b = [Y \quad -Y]$$

### Problem 3

a) Let  $w_1, w_2, w_3, \dots$  be an ordering of all strings in  $\Sigma^*$ .

for each  $i = 1, 2, \dots$

~~run~~  
~~if~~  
run  $M_1$  and  $M_2$  for each  $w_1, w_2, \dots, w_i$  up to  $i$  steps.

If  $M_1$  and  $M_2$  simultaneously accept at least  $k$  <sup>such</sup> strings  $\Rightarrow$  accept.

b) Reduce

$\overline{A_{TM}} \leq_M \overline{A}$  which implies that  $\overline{A}$  is not Turing-recognizable and  $A$  is not Turing-decidable.

On input  $\langle M, w \rangle$  to  $\overline{A_{TM}}$

construct machines  $M_1$  and  $M_2$  as follows

$M_1$  accept all languages in  $\Sigma^*$ .

$M_2$ , on input  $x$ ;

accepts iff  $M$  ~~does not~~ accepts  $w$ .

So, if  $M$  accepts  $w \Rightarrow L(M_2) = \Sigma^*$  and  $|L(M_1) \cap L(M_2)| \geq k$   
 $\langle M, w \rangle \notin \overline{A_{TM}}$  and  $\langle M_1, M_2, k \rangle \notin \overline{A}$

if  $M$  does not accept  $w \Rightarrow L(M_2) = \emptyset \Rightarrow |L(M_1) \cap L(M_2)| = 0$   
 $\langle M, w \rangle \in \overline{A_{TM}}$  and  $\langle M_1, M_2, k \rangle \notin \overline{A}$

#### Problem 4:

Take a string like that and split it into pieces •  
with form  $10^*$  plus a prefix of 0's.

Each piece  $10^*$  must not be 10 with the exception of  
the last piece.

Answer:  $0^*(1 \cup 1000^*)^*(10 \cup \epsilon)$

The DFA above is the minimum DFA for this language.

We took each solution and used a program to generate the  
minimum DFA and compared to the DFA above. You  
got credit if the minimum DFA for your regular expression  
matched the DFA above.

## Problem 5:

- a) Consider pairs of states  $(q, q')$  where  $q$  is state of  $D_1$  and  $q'$  " " "  $D_2$ .

Put edges ~~between~~ <sup>from</sup>  $(q, q')$  to  $(p, p')$  if there is a transition from  $q$  to  $p$  in  $D_1$  and from  $q'$  to  $p'$  in  $D_2$ . ~~if there exists a~~

path if  $L(D_1) \neq L(D_2)$  then there exists a path from  $(q_0, q'_0)$  to a state  $(q, q')$  where either  $q$  or  $q'$  (but not both) is a final state.

initial state of  $D_1$       initial state of  $D_2$

Clearly, such a path must have length  $\leq m_1 m_2$  which gives a string in  $(L(D_1) \cup L(D_2)) \setminus (L(D_1) \cap L(D_2))$ .

- b) We show that ~~the language is in~~ ~~NPSPACE~~  $\text{NPSPACE} = \text{PSPACE}$ .

Note that we can simulate an NFA in PSPACE since it suffices to keep track of the states the NFA is in.

We cannot convert it to a DFA since this <sup>may</sup> use exponential space.

Also, we cannot initially guess the string that distinguishes  $N_1$  and  $N_2$ , since the string may be exponentially large. But we can guess the string one symbol at a time. By lemma (a), string has at most  $2^{m_1} 2^{m_2} = 2^{m_1 + m_2}$

For each  $i = 1, 2, \dots, 2^{m_1 + m_2}$  { symbols, which can be stored in poly space.  
guess  $i$ -th symbol and update  $(m_1 = \# \text{ states of } N_1)$   
current states of  $N_1$  and  $N_2$ .  $(m_2 = \# \text{ " " } N_2)$ .

If ~~one~~ either  $N_1$  or  $N_2$  but not both is in an accepting configuration  $\Rightarrow$  accept.

}  
reject.

## Problem 6:

$A \in NL$ .

Linear grammars have only one non-terminal at the right-hand-side of each production. This means that, during the derivation, at any time, there exists only one variable to expand. We then guess the ~~derivation~~ derivation of that variable at each step.

Let  $w = w_1 w_2 \dots w_n$ . We keep two pointers  $i$  start and end which marks the # of symbols matched for the beginning and ending of  $w$ .

If the variable to be derived is  $X$  and we guess the rule  $X = a Y b$  where  $a, b \in \Sigma^*$  we do

if  $a = w_{start+1} w_{start+2} \dots w_{start+|a|}$

and  $b = w_{n-end-|b|+1} \dots w_{n-end}$  then

do  $start := start + |a|$

end  $:= end + |b|$

derive  $Y$

otherwise reject (wrong guess).

the pointers start and end, ~~require~~ and the pointer to the variable to be derived require only log-space.

### Problem 6 cont'd :

$A \in \text{NL-complete}$  reduce from PATH.

Let  $\langle G, s, t \rangle$  be an instance for PATH.

Each node of  $G$  is a variable of the grammar.

$s$  is the start variable.

For each edge  ~~$(u, v)$~~   $(u \rightarrow v)$  ~~with~~ add the rule  $u \rightarrow v$  to the grammar and add the rule  $t \rightarrow w$ .

Then, a path from  $s$  to  $t$  can be used to derive  $w$  and, if there exists no path from  $s$  to  $t$ , the grammar accepts no language.

### Problem 7:

the element at the tape head is always ~~marked with a dot in the queue~~ <sup>marked with a dot in the queue</sup>  
the element to the left of the tape head is recorded in the state as a buffer  
(element  $b$  is the hint). If tape head is the leftmost symbol then  $\text{buffer} = \$$ .  
 $\$$  marks end of tape.

~~\* Right move from  $(q, b)$  (follow example as hint)~~  
~~Pop and push symbols to queue until see dotted symbol  $\dot{c}$ .~~  
~~Let  $x$  be symbol to be written to TM.~~  
~~switch to state  $(q', x)$  where  $q'$  is the~~  
~~new state of TM.~~  
~~if  $b = \$$  then tape head is at the last cell.~~  
~~so we repeat~~

First pushed symbol is dotted unless this symbol is  $= \$$  for which case we first push  $\bar{L}$

### \* Left move from $(q, b)$

If  $b = \$$  we are in leftmost entry of cell.

if  $b \neq \$$   
Pop and push symbols to the queue remembering last symbol popped  
until dotted symbol  $\dot{c}$  is seen. Let  $y$  be remembered symbol.  
Push  $\bullet b$  and  $x$ , where  $x$  is the symbol to be written to tape head.  
switch to  $(q', y)$ , where  $q'$  is new state of TM.

If  $b = \$$  we do the same but  $y = \$$  and we do not push  $b$ .

### \* Right move from $(q, b)$

Pop and push until see dotted symbol, let  $x$  be symbol to be written to tape.  
Push  $b$ . Pop next symbol. If symbol  $= \$$ , push  $\bar{L}$  and  $\$$ .  
otherwise, push  $\bar{y}$   
<sub>symbol =  $y$</sub>   
switch to  $(q', x)$
